

BUSINESS OVERVIEW

Anypoint Watchmen

Always-on visibility of MuleSoft licence consumption, risky platform changes and what is running, so there are no surprises on the invoice or in the audit.

Hourly

Usage, audit and inventory refreshed automatically, instead of once a month on the invoice

9 + 5

Contract entitlements tracked against limits, plus extra metrics watched for awareness

~99%

Less audit-log noise, so reviewers only see changes that matter

Executive summary

MuleSoft is licensed by capacity: flows, messages, data throughput, API instances and more. The bill reflects what was consumed, but it arrives **after** the fact. By then an overage has already happened, and any risky change made in the platform has already gone unnoticed for weeks.

Anypoint Watchmen is a small, self-hosted monitoring application that closes that gap. Every hour it reads the organisation's usage, audit log and inventory from Anypoint Platform. It compares consumption with the contracted limits and alerts the right people by email when something needs attention.

In one sentence: Watchmen turns the monthly invoice and an unread audit log into a live dashboard and early-warning emails, so licence and governance decisions are made before they become problems.

The problem it solves

Today, without Watchmen	With Watchmen
Consumption is seen once a month, on the invoice.	Consumption is checked every hour and shown as "% of contract used".
Overages are discovered after they are billable.	Warning at 80% and critical at 95% of a limit, emailed automatically.
The audit log is thousands of logins, views and permission changes. Nobody reads it.	Routine events are filtered out at source. Risky changes are classified Critical or Warning and raise an alert.
"What is deployed where?" needs someone to click through several consoles.	One inventory view of business groups, environments, applications and APIs.
Evidence for renewals and audits is assembled by hand.	Month-by-month usage history and a classified change log are already stored.

What the business gets

- **Cost control:** early warning before contract limits are breached, and time to act (optimise, re-plan, or negotiate) instead of paying overage.
- **Governance and security:** deletions of applications, APIs, environments, policies or connected apps are surfaced within the hour.
- **Better renewals:** real consumption trends (peak and cumulative) to right-size the next contract.
- **Less manual effort:** no more monthly spreadsheet reconciliation or log trawling.

What it does

Watchmen has four capabilities. All of them run automatically every hour and can also be started on demand from the dashboard.

1 Licence & entitlement tracking

Reads consumption for every usage meter Anypoint exposes and compares it with the limits on the contract.

- **Contract entitlements** (for example Mule Flows, Mule Messages, Data Throughput, API Manager instances, Flex Gateway calls, IDP pages) show used / limit / % and a traffic-light status.
- Understands both licence models: **high watermark** (the peak counts) and **drawdown** (a pool used up over the contract).
- **Monitoring-only metrics** (such as LLM token usage) are shown for awareness and never raise alerts.

2 Audit log watch

Reads the platform audit log and keeps only the changes that matter.

- Logins, views, searches and permission changes are excluded **before** they are downloaded.
- Each remaining change is rated **Critical**, **Warning** or Info using business-defined rules.
- Only new events are fetched each hour, so nothing is missed or double counted.

3 Alerts & notifications

One alert list for both licence and audit risks, with a simple lifecycle.

- **Open → Acknowledged → Resolved**, managed from the dashboard.
- Licence alerts escalate (Warning → Critical) and close themselves when usage drops back.
- Audit alerts close themselves after 7 days (configurable).
- New alerts are emailed to a recipient list that business users can edit themselves.

4 Platform inventory

A current list of what exists in the organisation.

- Business groups and their hierarchy.
- Environments (production vs. sandbox).
- Deployed CloudHub 2.0 applications and their status and runtime version.
- API Manager instances per environment.

How it works

Watchmen only **reads** from Anypoint Platform. It cannot deploy, change or delete anything there.

Use cases

Each scenario below shows how Watchmen changes the outcome of a situation that platform teams meet regularly.

1. Avoiding a message overage

Finance · Platform owner

SITUATION

A new integration goes live and message volume grows faster than planned. The drawdown pool will run out before the contract ends.

WHAT WATCHMEN DOES

When Mule Messages reaches 80% of the pool, a Warning email goes out. At 95% the alert escalates to Critical.

OUTCOME

The team has weeks, not days, to optimise the integration or agree a top-up at a negotiated price instead of paying overage.

2. Catching a risky change

Security · Governance

SITUATION

Someone deletes a Connected App or an API policy, by mistake or deliberately.

WHAT WATCHMEN DOES

The change is rated Critical within the next hourly cycle. It is emailed with who did it, what and when.

OUTCOME

Incidents are detected the same day rather than when a consumer reports a failure. Accountability is clear.

3. Right-sizing the renewal

Procurement · Leadership

SITUATION

The MuleSoft contract is up for renewal and the vendor proposes new capacity figures.

WHAT WATCHMEN DOES

Provides month-by-month history of every meter: peaks for high-watermark items and cumulative use for drawdown items.

OUTCOME

The negotiation is based on evidence. Over-provisioned items can be reduced and under-provisioned ones planned for.

4. Reconciling the invoice

Finance

SITUATION

The monthly MuleSoft usage summary arrives and someone has to check it.

WHAT WATCHMEN DOES

Shows the same metrics, in the same order as the invoice, with Watchmen's own measured values.

OUTCOME

Differences are spotted quickly. Metrics not on the contract are visible but clearly separated.

5. Keeping demo and sandbox estates tidy

Presales · Platform owner

SITUATION

Demo apps and API instances pile up across business groups and quietly consume entitlements.

WHAT WATCHMEN DOES

The inventory lists every app and API instance by business group and environment, next to the entitlement it consumes.

OUTCOME

Unused items are found and removed, which frees capacity for real work.

6. Audit and compliance evidence

Compliance · Internal audit

SITUATION

An auditor asks for evidence that changes to production integrations are monitored.

WHAT WATCHMEN DOES

Keeps a classified log of significant changes and a record of every alert and how it was handled.

OUTCOME

Evidence is available immediately, with acknowledgement and resolution history.

Who benefits

Role	What they look at	Benefit
Platform / integration owner	Entitlement status, inventory, open alerts	One place to run the platform. Early warning on capacity.
Finance / procurement	Contract entitlements vs. invoice, usage history	No surprise overages. Evidence for renewals.
Security & governance	Critical / Warning audit alerts	Same-day visibility of destructive or sensitive changes.
Leadership	Overview tiles: alerts, entitlements at risk	Confidence that licence spend and platform risk are under control.
Delivery / presales teams	Inventory by business group	Know what is deployed and clean up unused assets.

What people see

The dashboard opens in any web browser. The overview looks like this (illustrative values):

Illustrative example. Real values come from your organisation's Anypoint usage data.

Business impact

The value of Watchmen comes from **acting earlier**. The figures below are facts about how the tool works. Financial savings depend on each organisation's contract and usage, so they are not estimated here.

~720×

more frequent view of consumption (hourly instead of monthly)

≤ 1 hour

from a risky change in Anypoint to an alert

~99%

less audit noise reviewed, by excluding routine events at source

0

changes made to Anypoint: read-only by design

Where the value comes from

Area	Impact
Avoided overage	Breaches of drawdown pools (messages, throughput, gateway calls, IDP pages) are flagged at 80% and 95%, while there is still time to optimise or negotiate a planned top-up.
Renewal savings	Accurate peak and cumulative figures support reducing over-bought capacity and avoiding emergency purchases.
Reduced incident impact	Destructive or sensitive changes are detected within the hour, which shortens the time integrations stay broken or exposed.
Staff time	Removes recurring manual work: invoice reconciliation, log reviews and inventory gathering across consoles.
Audit readiness	A stored, classified change history with alert handling records is available on request.

How to measure success

- Number of contract periods closed with **no unplanned overage**.
- Average time from a Critical audit event to acknowledgement.
- Hours per month saved on reconciliation and log review.
- Capacity reduced or reallocated at renewal based on Watchmen history.

Scope, limits and roadmap

In scope today

- One Anypoint organisation, including its business groups.
- Hourly collection of usage, audit log and inventory.
- Contract limits and alert thresholds held in configuration files.
- Email alerts. Recipients and audit settings are editable in the dashboard.
- Runs on a laptop/server (Anypoint Studio or Mule runtime) or in CloudHub 2.0.

Good to know

- Anypoint usage data arrives with roughly a **3-day delay**. That is fine for licence tracking but not real-time.
- Some usage meter names must be **confirmed once** against the organisation's Anypoint account during setup.
- The dashboard has no login of its own yet. Keep it on an internal network.
- Limits must be updated when the contract changes.

Roadmap candidates

Item	Why it matters
PDF / CSV export	Share monthly reports with finance and leadership without dashboard access.
Multiple organisations	One view across several Anypoint accounts or customers.
Inventory change alerts	Be told when apps or APIs appear or disappear, not only when limits are near.
Dashboard sign-in	Allow safe access beyond the internal network.
Forecasting	Predict the date a drawdown pool will run out at the current rate.

Next steps

- 1 **Nominate an owner** for Watchmen and the people who should receive alerts.
- 2 **Confirm contract figures** (limits, start and end dates) from the latest MuleSoft invoice.
- 3 **Platform admin creates a read-only Connected App** in Anypoint (about 15 minutes). See the Technical Setup Guide.
- 4 **Run Watchmen for two weeks** alongside the existing process and compare its figures with the invoice.
- 5 **Agree the alert response**: who acknowledges, who acts, and how quickly.
